

1.3

Studying Life

THINK ABOUT IT Think about important and exciting news stories you've seen or heard. Bird flu spreads around the world, killing thousands of birds and threatening a human epidemic. Users of certain illegal drugs experience permanent damage to their brains and other parts of their nervous systems. Reports surface about efforts to clone human cells to grow new organs to replace those lost to disease or injury. These and many other stories involve biology—the science that employs scientific methodology to study living things. (The Greek word *bios* means “life,” and *-logy* means “study of.”)

Characteristics of Living Things

 **What characteristics do all living things share?**

Biology is the study of life. But what is life? What distinguishes living things from nonliving matter? Surprisingly, it isn't as simple as you might think to describe what makes something alive. No single characteristic is enough to describe a living thing. Also, some nonliving things share one or more traits with organisms. For example, a firefly and fire both give off light, and each moves in its own way. Mechanical toys, automobiles, and clouds (which are not alive) move around, while mushrooms and trees (which are alive) stay in one spot. To make matters more complicated, some things, such as viruses, exist at the border between organisms and nonliving things.

Despite these difficulties, we can list characteristics that most living things have in common.  **Living things are made up of basic units called cells, are based on a universal genetic code, obtain and use materials and energy, grow and develop, reproduce, respond to their environment, maintain a stable internal environment, and change over time.**

FIGURE 1-12 Is It Alive? The fish are clearly alive, but what about the colorful structure above them? Is it alive? As a matter of fact, it is. The antlerlike structure is actually a marine animal called elkhorn coral. Corals show all the characteristics common to living things.

Key Questions

 **What characteristics do all living things share?**

 **What are the central themes of biology?**

 **How do different fields of biology differ in their approach to studying life?**

 **How is the metric system important in science?**

Vocabulary

biology • DNA • stimulus • sexual reproduction • asexual reproduction • homeostasis • metabolism • biosphere

Taking Notes

Concept Map As you read, draw a concept map showing the big ideas in biology.

VISUAL SUMMARY

THE CHARACTERISTICS OF LIVING THINGS

FIGURE 1-13 Apple trees share certain characteristics with other living things.

Compare and Contrast How are the apple tree and the grass growing below similar? How are they different?

Living things are based on a universal genetic code. All organisms store the complex information they need to live, grow, and reproduce in a genetic code written in a molecule called **DNA**. That information is copied and passed from parent to offspring. With a few minor variations, life's genetic code is almost identical in every organism on Earth.

The information contained in an apple tree's DNA directs all of the tree's life processes.

Living things grow and develop. Every organism has a particular pattern of growth and development. During development, a single fertilized egg divides again and again. As these cells divide, they differentiate, which means they begin to look different from one another and to perform different functions.

An apple tree develops from a tiny seed.

Living things respond to their environment.

Organisms detect and respond to stimuli from their environment. A **stimulus** is a signal to which an organism responds.

Some plants can produce unsavory chemicals to ward off caterpillars that feed on their leaves.

Living things reproduce. All organisms reproduce, which means that they produce new similar organisms. Most plants and animals engage in sexual reproduction. In **sexual reproduction**, cells from two parents unite to form the first cell of a new organism. Other organisms reproduce through **asexual reproduction**, in which a single organism produces offspring identical to itself.

Beautiful blossoms form as part of the apple tree's reproductive cycle.

Living things maintain a stable internal environment. Most organisms need to keep conditions inside their bodies as constant as possible, even when external conditions change dramatically. All living organisms expend energy to keep conditions inside their cells within certain limits. This process is called **homeostasis**.

These specialized cells help the leaves regulate gases that enter and leave the plant. SEM 1200X

Living things obtain and use material and energy. All organisms must take in materials and energy to grow, develop, and reproduce. The combination of chemical reactions through which an organism builds up or breaks down materials is called **metabolism**.

Various metabolic reactions occur in leaves.

Living things are made up of cells.

Organisms are composed of one or more cells—the smallest units considered fully alive. Cells can grow, respond to their surroundings, and reproduce. Despite their small size, cells are complex and highly organized.

Each plant structure consists of millions of cells. LM 800X

Taken as a group, living things evolve.

Over generations, groups of organisms evolve, or change over time. Evolutionary change links all forms of life to a common origin more than 3.5 billion years ago. Evidence of this shared history is found in all aspects of living and fossil organisms, from physical features to structures of proteins to sequences of information in DNA.

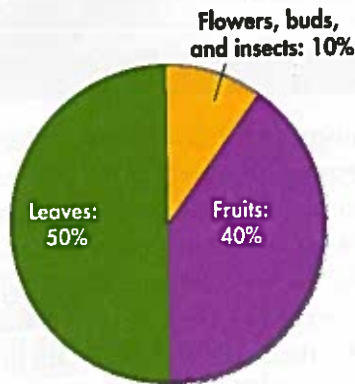

Signs of one of the first land plants, Cooksonia, are preserved in rock over 400 million years old.

Analyzing Data

What's in a Diet?

The pie chart shows the diet of the siamang gibbon, a type of ape found in the rainforests of Southeast Asia.

Analyze and Conclude

- 1. Interpret Visuals** Which plant parts do siamangs rely on most as a source of their matter and energy?
- 2. Predict** How would siamangs be affected if the rainforests they live in were cut down?

Big Ideas in Biology

What are the central themes of biology?

The units of this book seem to cover different subjects. But we'll let you in on a secret: That's not how biology works. All biological sciences are tied together by themes and methods of study that cut across disciplines. These "big ideas" overlap and interlock with one another, and crop up again and again throughout the book. You'll also notice that several of these big ideas overlap with the characteristics of life or the nature of science.

Key The study of biology revolves around several interlocking big ideas: The cellular basis of life; information and heredity; matter and energy; growth, development, and reproduction; homeostasis; evolution; structure and function; unity and diversity of life; interdependence in nature; and science as a way of knowing.

Big idea **Cellular Basis of Life** Living things are made of cells. Many living things consist of only a single cell; they are called unicellular organisms. Plants and animals are multicellular. Cells in multicellular organisms display many different sizes, shapes, and functions. The human body contains at least 85 different cell types.

Big idea **Information and Heredity** Living things are based on a universal genetic code. The information coded in DNA forms an unbroken chain that stretches back roughly 3.5 billion years. Yet, the DNA inside your cells right now can influence your future—your risk of getting cancer, the amount of cholesterol in your blood, and the color of your children's hair.

Big idea **Matter and Energy** Living things obtain and use material and energy. Life requires matter that serves as nutrients to build body structures, and energy that fuels life's processes. Some organisms, such as plants, obtain energy from sunlight and take up nutrients from air, water, and soil. Other organisms, including most animals, eat plants or other animals to obtain both nutrients and energy. The need for matter and energy link all living things on Earth in a web of interdependent relationships.

Big idea **Growth, Development, and Reproduction** All living things reproduce, which means that, in one way or another, they produce more individuals. Newly produced individuals are virtually always smaller than adults, so they grow and develop as they mature. During growth and development, generalized cells typically become more and more different and specialized for particular functions. Specialized cells build tissues, such as brains, muscles, and digestive organs, that serve various functions.

Big idea **Homeostasis** Living things maintain a relatively stable internal environment. For most organisms, any breakdown of homeostasis may have serious or even fatal consequences.

In Your Notebook Describe how a baby grows and develops.

Big idea **Evolution** Taken as a group, living things evolve. Evolutionary change links all forms of life to a common origin more than 3.5 billion years ago. Evidence of this shared history is found in all aspects of living and fossil organisms, from physical features to structures of proteins to sequences of information in DNA. Evolutionary theory is the central organizing principle of all biological and biomedical sciences.

Big idea **Structure and Function** Each major group of organisms has evolved its own particular body part “tool kit,”—a collection of structures that have evolved in ways that make particular functions possible. From capturing food to digesting it, and from reproducing to breathing, organisms use structures that have evolved into different forms as species have adapted to life in different environments. The structures of wings, for example, enable birds and insects to fly. The structures of legs enable horses to gallop and kangaroos to hop.

Big idea **Unity and Diversity of Life** Although life takes an almost unbelievable variety of forms, all living things are fundamentally similar at the molecular level. All organisms are composed of a common set of carbon-based molecules, store information in a common genetic code, and use proteins to build their structures and carry out their functions. One great contribution of evolutionary theory is that it explains both this unity of life and its diversity.

Big idea **Interdependence in Nature** All forms of life on Earth are connected into a **biosphere**, which literally means “living planet.” Within the biosphere, organisms are linked to one another and to the land, water, and air around them. Relationships between organisms and their environments depend on the cycling of matter and the flow of energy. Human life and the economies of human societies also require matter and energy, so human life depends directly on nature.

Big idea **Science as a Way of Knowing** Science is not a list of facts, but “a way of knowing.” The job of science is to use observations, questions, and experiments to explain the natural world in terms of natural forces and events. Successful scientific research reveals rules and patterns that can explain and predict at least some events in nature. Science enables us to take actions that affect events in the world around us. To make certain that scientific knowledge is used for the benefit of society, all of us must understand the nature of science—its strengths, its limitations, and its interactions with our culture.

FIGURE 1-14 Different But Similar

The colorful keel-billed toucan is clearly different from the plant on which it perches. Yet, the two organisms are fundamentally similar at the molecular level. Unity and diversity of life is an important theme in biology.

MYSTERY CLUE

What human values or biases are involved in the case of giving HGH to healthy children? What role does science play in this case?
